From Coaching Report to Regional Training Model: Extending *Rapport-FEP-Graz* Through the Talent Romandie Archive, 2016–2021

Demo package generated with the BFESP orchestrator skill

4 April 2026

Abstract

This article reconstructs and extends David Graz's 2016 coaching report *L'apport technique du freestyle au VTT XCO* as an archive-based contribution to youth Olympic cross-country mountain biking coaching. The source base combines the anchor report with representative Talent Romandie materials from 2018 to 2020, including programme notes, training plans and kick-off slide decks. The research question is not whether the original report can be converted into a conventional empirical paper, but which parts of it become academically defensible when read as the starting point of a later regional coaching model. The analysis shows three durable contributions. First, the 2016 report already articulated a coherent training-science logic linking athlete analysis, annual planning, competition preparation and technical development. Second, later Talent Romandie documents institutionalized that logic around a stable triad: technical priority, athlete evaluation and structured training. Third, the archive makes implicit sport-psychological mechanisms more visible, especially autonomy support, confidence building, concentration, fatigue monitoring and family–coach coordination. The article argues that the strongest originality claim is historical and conceptual rather than causal: the archive documents how a practice-based coaching text evolved into an organizational model for youth XCO development. The paper therefore contributes an evidence-disciplined extension of the original report while keeping its practical coaching core intact.

Keywords: youth cycling; Olympic cross-country; coaching systems; technical development; Talent Romandie; archive-based analysis

1 Introduction

Youth Olympic cross-country mountain biking (XCO) coaching sits at the intersection of endurance preparation, technical skill acquisition, talent development and family-supported progression. In such environments, coaching knowledge often circulates through internal reports, annual plans, presentations and evaluation tools rather than through journal articles. The BFESP orchestrator is useful precisely for this kind of case: it can treat a dense practical report as an anchor document, connect it to a broader archive, and test whether the resulting synthesis supports a stronger academic contribution.

The anchor text in this demonstration is David Graz's 2016 final coaching report for the Swiss professional coach pathway, built around Talent Romandie as a regional development setting and Amandine Deschenaux as an illustrative athlete case (Graz 2016). The report is broad by design. It covers discipline analysis, athlete and competition analysis, annual planning, a training intervention focused on downhill technique, a competition analysis based on lap times, and a concluding freestyle-informed technical chapter. Its practical ambition is explicit: to offer solutions to training-science problems while simultaneously rethinking technical development through a multidisciplinary view of the bicycle as both sporting tool and medium of movement (Graz 2016).

The central question of this article is therefore: what becomes academically valuable when *Rapport-FEP-Graz* is read not as an isolated coaching manuscript, but as the conceptual starting point of a later Talent Romandie training model? The article thesis is that the report's real strength lies in the coherence of its coaching logic and in the way later Talent Romandie documents partially institutionalize that logic. Between 2018 and 2020 the archive shows a clear organizational consolidation around three linked priorities: technique first, systematic evaluation of athletes, and increasingly structured training (Talent Romandie 2018; Talent Romandie 2019; Talent Romandie 2020). What was still an ambitious coaching proposition in 2016 appears, in the later archive, as a regional operating model.

This demonstration does not claim to convert the archive into causal evidence of programme effectiveness. The available material is too partial, too practice-oriented and too heterogeneous for that. Instead, the article makes a narrower but defensible claim: the archive allows a historically grounded, conceptually sharper reading of the original report. It becomes possible to distinguish what is preserved coaching know-how, what later documents strengthen, what remains speculative, and what can be reframed as a contribution to youth XCO coaching knowledge.

The article proceeds in eight steps. It first locates the report in its institutional context. It then explains the archive-based analytical framework. Next, it offers a global synthesis of the 2016 report. The following section reconstructs the historical extension visible in the Talent Romandie archive from 2018 to 2020. Two analysis sections then reinterpret the material through coaching-systems and performance-psychology lenses. The discussion formulates the article's originality claim and boundaries. The conclusion returns to the initial question and identifies a next research step.

2 Background and Original Report Context

The 2016 report was written inside the Swiss coach education pathway and uses Talent Romandie as its practical reference environment (Graz 2016). Talent Romandie is described as an independent Romand cycling structure affiliated with Swiss Cycling, bringing together route, track and mountain-bike youth squads to create better inter-disciplinary synergies. In the report's own description, the group gathered talented athletes aged roughly 14 to 18 and aimed to support both sporting and educational development through camps, competition accompaniment, planning support and access to multidisciplinary practice (Graz 2016).

This context matters because the report is not a thesis in the classic academic sense. It is a coach formation document written at the boundary between formal training science and

field intervention. Its authorial objective is explicitly double. On one side, the document wants to address classic training-science issues: discipline analysis, load management, periodization, macrocycles, microcycles, training interventions and competition measures. On the other side, it wants to improve technical riding by looking at freestyle and other bike disciplines as sources of technical innovation (Graz 2016). The report therefore mixes internal evidence, literature references, observation, applied reasoning and pedagogical proposals.

The original coaching setting is also significant because it sits inside a Swiss talent pathway that values long-term development, progressive specialization, technical competency and coordination-rich training in the earlier years (Graz 2016). In the report, Talent Romandie functions less as a stand-alone high-performance team than as a complement to club coaching and family environments. Athletes remain embedded in their clubs and homes; the regional structure supplies specific expertise, camps, planning support and institutional legitimacy. That ecological positioning is central to the later extension developed in this article.

Historically, the report emerged at a moment when XCO courses were becoming more technical and television-friendly, pushing youth coaching away from purely physiological preparation toward broader technical literacy. Graz responds to that pressure by arguing for proactive riding, body-bike dissociation, movement variability and selective borrowing from BMX, downhill, pumptrack and trail cultures (Graz 2016). The report thus belongs to a strand of coaching literature that is highly practical, concept-rich and field-driven, but not yet formalized in journal language.

Later Talent Romandie documents suggest that this 2016 baseline did not disappear. A 2018 programme note identified low technical level as one reason for weak Romand presence in national top-30 results and proposed a clear corrective strategy: more weekend training days, more cross-disciplinary technical sessions, warm-up and workshop routines based on the Swiss Cycling motor test, and evaluation-linked talent-card decisions (Talent Romandie 2018). By 2019 the organization described itself as having already increased training opportunities from four to seventeen, introduced continuous athlete evaluation, strengthened technical content and created a more explicit Romand selection identity (Talent Romandie 2019). In 2020 the kick-off deck represented the project as a triangle built on "priority to technique", "evaluation of athletes" and "structured training" (Talent Romandie 2020). These later sources transform the background context: the 2016 report can now be read as an early formulation of a model that later became organizationally visible.

3 Analytical Framework and Corpus

This article uses a small but purposeful archive-based design. The anchor document is the uploaded *Rapport-FEP-Graz-digital.pdf*, supplemented by mirrored Google Drive copies. The second evidence layer is made of representative Talent Romandie archive materials that materially change the interpretation of the anchor report: the 2018 training directions note, the 2019/20 programme document, and the 2020/21 kick-off slide deck (Graz 2016; Talent Romandie 2018; Talent Romandie 2019; Talent Romandie 2020). Together these sources offer continuity across four moments: initial conceptualization (2016), operational redirection (2018), programme consolidation (2019) and organizational formalization (2020).

The analytical logic follows the BFESP orchestrator specification. First, the anchor PDF is treated as a whole rather than mined for isolated quotations. This matters because the report's value lies in internal architecture: discipline analysis, athlete analysis, annual planning, training intervention, competition interpretation and technical innovation are designed to cohere. Second, later archive documents are classified according to whether they act as conceptual continuation, methodological support, historical context or reinterpretation. Third, the material is read through five expert lenses: cycling coaching, sports coaching, performance sport psychology, freestyle sport, and Olympic XCO specificity. In this demonstration those lenses are integrated into the prose rather than presented as separate memoranda.

The corpus remains partial. Not every annual file could be parsed cleanly. Some spreadsheets were unavailable through the connector in reusable form, and some yearly folders contain administrative or presentation material that is less analytically relevant than the programme documents themselves. This article therefore does not claim exhaustive archive coverage. Instead, it uses a representative chain of documents that are sufficient to test whether the core ideas of the 2016 report persisted, intensified or changed over time.

Three evidence principles structure the interpretation. First, direct claims about the original report are attributed to the anchor text. Second, historical extension claims are attributed to later archive documents. Third, interpretive claims are explicitly framed as reconstruction rather than direct empirical findings. This distinction is especially important in the psychological section, where many mechanisms are implicit rather than formally measured.

A brief corpus map helps clarify the role of each source. The 2016 report supplies the full coaching architecture and the technical-freestyle argument (Graz 2016). The 2018 note supplies a strategic diagnosis of weak technical level, under-representation in national results and a proposed turn toward more structured technical work and evaluation (Talent Romandie 2018). The 2019 programme shows the same model after expansion: more sessions, continuous evaluation, explicit camp criteria and the addition of physiological work tied to technical parcours (Talent Romandie 2019). The 2020 kick-off slides quantify the organization, formalize the coach committee, show continuity of values and objectives, and still place technique, evaluation and structured training at the center (Talent Romandie 2020).

Because the archive is practice-generated, the method is interpretive synthesis rather than hypothesis testing. The goal is not to prove that each intervention caused later results. The goal is to reconstruct a credible developmental narrative and to decide which parts of that narrative can support a stronger academic article. Under those conditions, archive heterogeneity becomes a feature rather than a defect: it reveals how coaching knowledge moves from report to programme to slide deck to institutional routine.

4 Global Synthesis of *Rapport-FEP-Graz*

The 2016 report is most convincing when read as an internally coherent coaching system. Its first contribution is diagnostic. Graz begins with a broad analysis of road and mountain-bike demands, national and international competition structures, long-term development logic and training load by age category (Graz 2016). This opening grounds the report in the institutional reality of Swiss Cycling and avoids treating youth XCO as an isolated discipline. The emphasis

on endurance, force, speed, technical-coordinative capacities and psychological readiness is conventional, but the report already shows an interest in how those elements interact rather than operate in isolation.

The second contribution is ecological. The description of Talent Romandie highlights a developmental setting where clubs, families, individual coaches and the regional structure coexist rather than replace one another (Graz 2016). This is where the report becomes more than a technical manual. Graz repeatedly argues that the regional structure should complement the athlete's environment, supply specific expertise, and avoid destabilizing personal planning. Even before the later archive makes this clearer, the 2016 report is already trying to solve a classic youth-performance problem: how to add structure without over-centralizing the athlete.

Third, the report contains a robust planning logic. The annual planning section for Amandine Deschenaux is detailed and pedagogically explicit. It distinguishes process, performance and outcome goals; connects them to SMART logic; and lays out periodization through general preparation, specific preparation, pre-competition, competition and regeneration phases (Graz 2016). The report also uses load-monitoring instruments such as the Borg CR10 scale, the Foster model, monotony and mood/fatigue indices. Even if these tools are discussed in practical rather than methodological language, the reasoning is serious: training must be varied, monitored and matched to developmental level.

Fourth, the report is unusually strong on technical training for a document framed within endurance sport. The training intervention section argues that modern XCO increasingly requires fine riding skill, obstacle management, proactive body positioning and efficient descending. The proposed camp model uses downhill, pumptrack, North Shore, bunny-hop and nose-turn work not as spectacle, but as a way to improve the rider's relation to the bicycle (Graz 2016). This is already a broader claim than "technique matters": the report suggests that technical quality can reshape effort distribution, confidence and tactical options.

Fifth, the competition section adds pacing logic to the picture. Graz treats race analysis not simply as results reporting but as a way to reason about effort regulation. He uses split times and differential gaps to show that better outcomes are associated with more stable pacing and stronger final laps, then translates that observation into training implications about intensity control and competition experience (Graz 2016). This is one of the report's clearest bridges between field observation and coaching prescription.

The final and most original contribution is the freestyle chapter. Here the report argues that XCO technique can be strengthened by borrowing from BMX, pumptrack, downhill and other freestyle-derived practices. The key ideas are body-bike dissociation, proactive riding, movement decomposition, free exploration, flat pedals, lowered saddles and a multidisciplinary technical model built from movement primitives rather than discipline silos (Graz 2016). Academically, this section overreaches if read as proof of causal transfer. Practically, however, it is the part of the report that most clearly anticipates later skill-acquisition debates.

The same section also exposes the report's limitations. Evidence remains mostly observational, experiential and case-based. Psychological mechanisms are present but under-formalized. The athlete case is rich for coaching reflection but not for generalizable inference. And the proposed multidisciplinary technical model is more a conceptual scaffold than a validated frame-

work. Yet these weaknesses are precisely why the later archive matters. It shows that the report's strongest ideas were not abandoned; they were partially routinized.

5 Historical Extension from BFESP and Talent Romandie Archives

The later archive does not merely repeat the 2016 report; it clarifies how its logic was operationalized. The 2018 training directions note is the first clear turning point. It states that Romand athlete presence in national rankings is not representative of the region's potential and explicitly identifies technical level as one explanation for weak top-30 representation (Talent Romandie 2018). The proposed response is revealing: more training days, stronger athlete engagement, and a larger place for mixed technical sessions linking enduro, trial, BMX and downhill to XCO. The document also proposes that every training day include a Swiss Cycling motor-test based warm-up or workshop and that talent-card distribution be tied not only to results but also to attendance and coach-rated engagement (Talent Romandie 2018). In other words, the archive shows the 2016 freestyle and monitoring ideas being embedded into organizational procedure.

The 2019/20 programme makes the institutional shift even clearer. It explicitly states that training opportunities increased from four to seventeen, that a continuous evaluation system was introduced, that technical work remained central, and that the next step was to add physiological sessions adapted to competition (Talent Romandie 2019). The text is important because it does not abandon technique in favor of physiology; it subordinates physiology to a technically structured environment. Anaerobic work is to be performed in association with coordination and technical parcours. The first seasonal phase remains endurance and technique heavy, while the second introduces more explosive and anaerobic material with strong technical demands (Talent Romandie 2019). This directly extends the 2016 argument that XCO preparation should combine variable pacing demands with technical competence.

The 2019 programme also formalizes participation and camp criteria. Entry into later phases and camps depends on Swiss Olympic card status or training evaluation thresholds; maintenance in the squad depends on average evaluation and coach approval; selection for CEJ Pila combines attendance, evaluation, Swiss Bike Cup results, championship results, current form and coach judgment (Talent Romandie 2019). This marks an important transition from informal coaching culture toward structured decision-making.

The 2020/21 kick-off deck shows a further layer of consolidation. It lists a committee and coaching staff across disciplines, including David Graz as VTT coach and responsible trainer, and presents the kick-off programme as a mixed event for athletes, parents and committee members with an external intervention by Cyrille Gindre (Talent Romandie 2020). That alone matters historically: the coaching model is no longer only about athlete sessions, but also about stakeholder alignment.

More importantly, the slide deck makes the model legible in symbolic form. One slide presents Talent Romandie as a pyramid built on "priority to technique", then "evaluation of athletes", then "structured training" (Talent Romandie 2020). Another slide quantifies the organization: one official structure, four disciplines, twenty-seven athletes, five coaches, roughly 455 hours of training and substantial follow-car mileage, while also signaling the impact of pandemic disruption on race days (Talent Romandie 2020). Additional slides show continuity of values—respect,

confidence and performance—and set 2021 targets such as a twenty-point MotorikTest average, twenty athletes in the national top twenty and four athletes in the championship top five (Talent Romandie 2020). A results slide claims a sharp rise in motor-test scores from 2018 to 2019 and summarizes championship placements in 2019 and 2020 (Talent Romandie 2020).

Taken together, these documents show both continuity and change. What remained stable was the conviction that technical development should be central in youth XCO preparation. What evolved was the degree of structure: evaluation systems, participation thresholds, coach committees, quantified objectives, parent-facing communication and mixed technical–physiological planning. What intensified was the ambition to transform a regional complement into a recognizable development model. What may already have become dated is some of the language of talent selection and motor-test dominance, which would need critical discussion in a final research article. But the archive undeniably strengthens one historical claim: the 2016 report anticipated a later organizational pattern rather than standing alone.

6 Coaching Systems and Technical Development Analysis

From a cycling-coaching perspective, the report and archive are strongest when periodization and technical development are read together. The 2016 report uses classic periodization language, indebted to training-science texts such as Platonov and Grappe, but the later archive shows that the practical center of gravity was not abstract macrocycle design alone. It was the repeated coupling of technical tasks, controlled series, evaluation routines and staged seasonal progression (Platonov 1988; Grappe 2012; Graz 2016; Talent Romandie 2019). That coupling is especially relevant for youth XCO because the discipline requires repeated supra-threshold surges, tactical positioning and high technical control under fatigue (Abbiss and Laursen 2008; Graz 2016).

The main coaching-system insight is ecological rather than merely physiological. Talent Romandie appears as a regional complement to club and family environments, not a total institution. That principle is already explicit in the anchor report and remains visible in later materials that integrate parents into kick-off communication and selection logic (Graz 2016; Talent Romandie 2020). As a generalizable principle, this is valuable: youth performance structures can add specificity, evaluation and identity without entirely displacing local coaching relations.

Technical development is the area where the archive most clearly confirms the original report. The 2018 note diagnosed technical weakness and proposed mixed sessions across enduro, trial, BMX and downhill (Talent Romandie 2018). The 2019 programme operationalized those ideas through named technical exercises, motor-test routines, technical series and a camp structure built around pumptrack, descending, North Shore and CEJ preparation (Talent Romandie 2019). The 2020 deck reduced the whole model to an organizational slogan: technique first, then evaluation, then structured training (Talent Romandie 2020). This sequence matters. It implies that technical skill is not a decorative addition to endurance training, but the organizing basis on which evaluation and structured workload rest.

From a freestyle-sport perspective, the report's most useful claim is also its most delicate. The strongest practical idea is not that BMX or downhill mechanically transfer performance to XCO. It is that those disciplines create learning situations rich in balance, body-bike dissociation, movement variability, free exploration and proactive riding. In the report, flat pedals, lowered

saddle work and time for non-linear experimentation are pedagogical tools, not subcultural ornaments (Graz 2016). The archive supports the persistence of that pedagogical orientation, although it does not prove the magnitude of its effects.

The XCO-specific lens sharpens the point further. Modern XCO demands climbing power, repeated accelerations, technical precision in descents, and tactical position management after mass starts. The 2016 report correctly links early surges, pacing and technical economy; the later archive adds an organizational answer by embedding physiological work inside technical contexts rather than treating technical and physical preparation as separate worlds (Graz 2016; Talent Romandie 2019). That is arguably the most publishable coaching insight in the whole package.

What should not be generalized too quickly is the evaluation system itself. Attendance, coach judgments and motor-test performance are helpful within a regional programme, but they may not travel cleanly across settings with different athlete populations, resource levels or institutional expectations. The article therefore preserves the coaching principle—structured complementary development with technique-centered planning—while treating the exact evaluation regime as context-bound.

7 Performance Sport Psychology Analysis

Sport psychology is everywhere in the source base, but rarely named as such. The 2016 report repeatedly discusses confidence, concentration, motivation, fatigue perception, emotional state and the role of family support, yet these variables remain mostly embedded in coaching language (Graz 2016). The archive makes them more legible by showing how organizational routines were built to shape athlete behavior and not just athlete physiology.

A first mechanism is autonomy support. Graz repeatedly argues that the regional structure should not destabilize the athlete's environment and should leave room for the athlete to find an "optimal evolution" while remaining available for support (Graz 2016). This is psychologically meaningful. It aligns with the idea that durable motivation is strengthened when athletes experience autonomy, competence and relatedness rather than constant external control (Deci and Ryan 2000). Even the later evaluation system, which could look controlling on paper, sits inside a context where the regional squad complements clubs and families rather than replacing them.

A second mechanism is competence construction through technique. The report's technical camps are not only about movement efficiency. They are also designed to increase assurance on the bike, improve obstacle management and create conditions where athletes can feel more capable under demanding terrain conditions (Graz 2016). The archive continues this logic when it ties training identity to technique first and uses repeated motor-test exercises to make progress visible (Talent Romandie 2018; Talent Romandie 2019; Talent Romandie 2020). Confidence in this material is not treated as abstract self-belief; it is built through repeated, observable mastery experiences.

A third mechanism is self-regulation of effort and fatigue. The 2016 report uses Borg ratings, Foster load estimates, monotony, mood scales and fatigue indices to keep athletes attentive to their sensations and to anticipate overload (Graz 2016). This is one of the report's most psychologically sophisticated elements, even if it is presented in physiological language. The

coaching problem is not only to produce training load; it is to help young athletes read their own responses to load. That is particularly relevant in adolescence, where school pressures, family organization and changing identity can interfere with performance routines.

A fourth mechanism is concentration and attentional control. In both the competition and technical sections, the report assumes that technical quality deteriorates if athletes mismanage pace, stress or terrain reading (Graz 2016). The later archive responds with structured warm-ups, ritualized training formats and coach evaluation. These are not merely administrative devices. They create attentional scaffolds. Athletes are repeatedly placed in environments where they must connect instruction, movement quality and self-monitoring.

The main psychological gap is the lack of formal constructs and systematic measures. The report never fully theorizes family coaching dynamics, developmental transitions, peer climate or stress regulation, even though all of them are visible in practice. The 2020 kick-off inclusion of parents and external speakers hints at a broader psychosocial project, but the archive does not yet provide enough material to claim a full sport-psychology programme (Talent Romandie 2020). Therefore the defensible contribution is not that Talent Romandie solved the psychological dimension. It is that the archive allows us to formalize psychological processes that were already embedded in the coaching design.

8 Discussion and Originality Claim

The central originality claim of this article is deliberately modest. It is not that *Rapport-FEP-Graz* becomes an empirical proof-text once connected to the archive. It is that the archive changes how the report can be read. Instead of appearing as a one-off coaching manuscript with ambitious technical ideas, it can be reconstructed as an early formulation of a later regional training model centered on technique, evaluation and structured complementary development (Graz 2016; Talent Romandie 2018; Talent Romandie 2019; Talent Romandie 2020).

That contribution is academically useful for at least three reasons. First, it demonstrates how practice-generated documents can support a defensible coaching-science article when interpreted with archive discipline. Many useful coaching ideas live outside journals; the problem is not their absence of value, but the absence of a framework that distinguishes preserved know-how from overclaiming. Second, it contributes specifically to youth XCO coaching by showing how technical development, physiological training and organizational design were progressively linked inside one regional structure. Third, it clarifies that sport-psychological mechanisms were not absent from the original report; they were implicit and embedded in coaching procedure.

The article also makes a methodological point. Archive-based reconstruction should not flatten all sources into the same status. The 2016 report is an anchor text. The 2018–2020 documents are primary organizational materials. Secondary training-science and psychology literature provides framing rather than decisive proof (Platonov 1988; Grappe 2012; Deci and Ryan 2000; Abbiss and Laursen 2008). This separation matters because coaching archives are especially vulnerable to retrospective myth-making. Once later success or organizational identity enters the narrative, it becomes easy to read earlier documents as prophetic. The present article resists that temptation. It shows continuity, but it does not claim inevitability.

The main unresolved weakness is evidentiary balance. The archive is not complete, some

results claims remain internally produced, and some spreadsheets and annual evaluation tools were only partially accessible. The article therefore avoids strong causal claims such as "technical-first training caused later performance gains". A more ambitious paper would need fuller yearly coverage, athlete-level longitudinal data, and direct testimony from coaches and athletes.

The freestyle contribution deserves special caution. It is arguably the most original practical section of the 2016 report, but also the easiest to exaggerate. The safest academic formulation is that freestyle-related disciplines offered Talent Romandie a richer repertoire of technical learning situations and a vocabulary for proactive riding, body-bike dissociation and movement decomposition. That is already an important contribution. It does not need inflated causal language to remain valuable.

On balance, the article shows that the archive materially extends the 2016 report in a way that is both historically interesting and coach-scientifically relevant. The strongest takeaway is not a new universal theory of youth cycling. It is a documented case of how a regional programme translated a practice-based technical vision into structured coaching routines over time.

9 Conclusion

This demonstration asked what becomes academically valuable when David Graz's 2016 coaching report is read together with later Talent Romandie materials. The answer is twofold. First, the anchor report already contains a coherent and unusually rich coaching architecture linking discipline analysis, periodization, technical intervention, competition reasoning and a freestyle-informed model of skill development. Second, the 2018–2020 archive shows that core elements of that architecture were later institutionalized in Talent Romandie through technique-centered planning, continuous evaluation and increasingly structured training.

The article's contribution is therefore historical, conceptual and applied. It does more than summarize the 2016 report, but it stops short of claiming causal proof. It shows how a practice-generated coaching text can be extended into an archive-based sport-science article without losing its field logic. For youth XCO coaching, the most useful implication is that technical development, physiological preparation and psychosocial support are strongest when designed as one ecological system rather than as separate coaching domains.

The next research step is clear. A fuller study should widen the archive to additional years, recover athlete-level evaluation tools and interview the coaches who translated the 2016 ideas into later routines. That would allow the historical reconstruction offered here to become a more complete account of regional youth cycling development in Romandie.

A Archive Notes

Primary materials used for this demonstration-scale package were the 2016 anchor report, the 2018 training directions memo, the 2019/20 programme document and the 2020/21 kick-off slide deck. The package is intentionally evidence-disciplined: it preserves the archive's strongest claims and narrows claims that would require fuller empirical support.
